

Heim Drive Type II: Kontrabaric Oscillation Drive

Core Concept:

- Heim–Dröscher extension proposes that polymetric field curvature can be modulated dynamically.
- If done rapidly, inertial reference frames within $\mathcal{R}^4$ become locally distorted.
- Result: acceleration from within the field zone — without Newtonian reaction mass.

Mechanism: Use oscillating external fields to trigger modal transitions within polymetric zones.

$$\delta \kappa_{ij}^{(\mu)}(t) \Rightarrow \Delta \Gamma_{jk}^i \Rightarrow \Delta a_{\text{eff}}$$

where $\kappa^{(\mu)}$ is the polymetric tensor governing modal curvature.
