

Kontrabaric Oscillation: Toward a Lab Test

Feasibility Approach:

- Construct an oscillating high-Q field cavity with toroidal symmetry.
- Apply synthetic selector modulations via EM pulses or phase plates.
- Use superconducting layers to isolate modal zones from classical leakage.

Expected Effects:

- Mass fluctuation ($\pm$),
- Directional inertial anomaly,
- Internal acceleration measurable without external interaction.

Warning: This drive is nonlinear — must be tested in full field configuration. Single-point analysis will fail.
