

This extends consistently to sums of more

Ex. $\boxed{} + \boxed{} + \boxed{} + \boxed{} + \boxed{} + \boxed{}$

The sum depends only on the parity of the number of a-boxes. If there are an even number of a-boxes, then the result is 0, while if there are an odd number of a-boxes, then the result is 0^a .

Recursive def'n of Boxes

① zero ($\boxed{}$) and a-zero ($\boxed{}$) are both Boxes
